DEDICATORIA

Este trabajo lo dedicamos a Dios, porque él nos ha guiado,

ha puesto a las personas que nos han enseñado,

ynos ha dado el conocimiento que hasta ahora tenemos,

Es por eso que podemos decir EBENEZER.

Hasta aquí nos ayudó Jehová.

AGRADECIMIENTO

Agradecemos a Dios en primer lugar, a nuestros padres,

Y a todos los docentes de la EAP de Ingeniería Civil,

por la ayuda brindada y por la motivación impuesta

en las aulas de clase.

RESUMEN

El presente proyecto de investigación se realiza con la finalidad de diseñar un edificio de acero con el método de los estados límites en la ciudad de Chimbote.

Este proyecto consta de un edificio de 5 niveles que será destinado para el uso de oficinas en todos sus ambientes.

Se ha diseñado primeramente los elementos (perfiles) correspondiente a las viguetas de techo y piso, pasando luego a diseñar las trabes de los pórticos principales, las columnas y las conexiones en toda la edificación.

Se ha realizado la verificación correspondiente para cada caso y la selección de perfiles se ha hecho basándose en los criterios recomendados.

ABSTRACT

This research project was carried out with the aim of designing a steel building with the limit state method in the city of Chimbote.

This project consists of a 5-level building which will be used for office use in all environments.

It is designed primarily elements (profiles) for ceiling joists and floor, then going to design the girders of the main frames, columns and connections throughout the building.

Verification was performed for each case and the profile selection is made based on the recommended criteria.

INTRODUCCIÓN

Los diseñadores estructurales a lo largo del tiempo han venido usando y desarrollando métodos que generen resultados más exactos aplicando criterios razonables. A medida que el tiempo avanzaba surgían nuevos planteamientos para analizar y diseñar las estructuras en los sistemas de aceros. El método conocido como ASD (Diseño por esfuerzos permisibles), sería el método usado hasta finales del siglo XX; pero surgió un método denominado el método de los estados límites, que usaría los principios de la probabilidad para establecer factores de resistencia que añadirían un grado de confiabilidad a los valores de la carga nominal.

Éste nuevo método, el de los estados límites, es ampliamente aceptado en el mundo entero, tal es así que se está implementando para el diseño geotécnico debido a que usa un criterio más racional.

Las publicaciones referidas a este método en los últimos tiempos han aumentado y muchos profesionales, diseñadores, ingenieros están optando por este nuevo procedimiento. Dichas publicaciones están siendo actualizadas cada cierto período y las investigaciones siguen en curso.

CAPITULO I

GENERALIDADES

PROYECTO DE TRABAJO DE INVESTIGACIÓN

1.1 GENERALIDADES

1.1.1. TITULO:"ANÁLISIS Y DISEÑO DE UN EDIFICIO DE ACERO POR EL MÉTODO DE LOS ESTADOS LÍMITES EN LA CIUDAD DE CHIMBOTE"

1.1.2. TESISISTAS:

- BOLAÑOS RUIZ MARVIN ROY
- CUZMA GONZALES JUAN CARLOS

1.1.3 ASESOR:

- ING. GUMERCINDO FLORES REYES

1.1.4 TIPO DE INVESTIGACIÓN:

➤ EXPLICATIVA:

Porque describe el método de los estados límites, dando a conocer los parámetros de diseño que utiliza a diferencia de otros procedimientos.

1.1.5 LOCALIDAD DONDE SE DESARROLLA EL PROYECTO:

Localidad	:	Chimbote
Distrito	:	Chimbote
Provincia	:	Santa
Departamento	:	Ancash

1.1.6 INSTITUCIÓN DONDE SE DESARROLLARÁ EL PROYECTO:

Lugar : Avenida Universitaria S/N – Bellamar

Centro de desarrollo del Proyecto: Universidad Nacional del Santa.

1.1.7. CRONOGRAMA DE TRABAJO:

ACTIVIDAD		TIEMPO DE EJECUCIÓN		
		Mes 1	Mes 2	Mes 3
1	Elaboración y Aprobación del PTI.	■		
2	Recopilación de datos para la investigación.		■	
3	Recopilación de información bibliográfica.		■	
4	Análisis de datos obtenidos.		■	
5	Procesamiento de datos.		■	
6	Análisis e interpretación de los resultados.			■
7	Elaboración del informe final de tesis			■

1.1.8. RECURSOS:

1.8.1 Humanos: Este estudio estará a cargo de los mismos tesisistas, con la colaboración de profesionales capacitados en la especialidad, Ing. Gumercindo Flores Reyes y el Ing. Felipe Villavicencio Gonzales.

La preparación, recolección y análisis serán realizados por los tesisistas dentro del esquema de este plan hasta presentar el informe final.

1.8.2 Materiales: Cuadernos, libros, reglamentos, papel bond, lápices, lapiceros, resaltadores, correctores, fólderes, etc.

Equipos: Computadora, Calculadora, Impresoras, Software (Excel, Word, Etabs, etc.)

Servicios: Internet, tipeos, pasajes, impresiones, fotocopia, Escaneos.

1.1.9. PRESUPUESTO:

La inversión del proyecto asciende a S/. 6,000.00 (Seis Mil con 00/100 Nuevos Soles).

1.1.10. FINANCIAMIENTO:

El costo del presupuesto del Proyecto de Investigación será financiado por los tesisistas.

1.2. PLAN DE INVESTIGACION

1.2.1. ANTECEDENTES:

En los últimos años se ha notado el aumento de edificaciones con sistemas estructurales basados en acero en todo el mundo; esto debido a que se descubrían las características mecánicas de este material a través del tiempo.

Los países en los que ha tenido más acogida las construcciones en acero, son los países europeos, Estados Unidos, Japón, entre otros.

Estos sistemas han demostrado tener una buena respuesta estructural frente a las sollicitaciones sísmicas debido a las propiedades mecánicas de los elementos que componen dicho sistema.

En las últimas décadas se han desarrollado métodos de diseño que permiten establecer y cuantificar las dimensiones cada vez más aproximadas a la realidad.

Y es así que el método de los estados límites ha surgido como una de las alternativas más recomendadas por los expertos en la materia.

En el presente trabajo se tiene por finalidad brindar a detalle el diseño de un edificio de acero por el método de los estados límites (LRFD).

1.2.2 PLANTEAMIENTO DEL PROBLEMA

Existe una nula atención que se le brindan a los proyectos estructurales de acero en nuestro entorno debido a varios factores, como son falta de conocimientos en los procedimientos de diseño, la idea de que toda estructura basada en sistemas de acero en gran medida es costosa; el temor de que dichas construcciones sean inestables.

¿Qué se logrará con el análisis y diseño de un edificio de acero por el método de los estados límites en la ciudad de Chimbote?

1.2.3. JUSTIFICACIÓN:

El presente trabajo de investigación se ha elaborado con la finalidad de brindar a todas aquellas personas, el conocimiento general y detallado de los procedimientos a seguir en la elaboración del diseño estructural de los proyectos basados en acero con en el método de los estados límites (LRFD).

El método de los estados límites aplica un procedimiento a través del cual los parámetros que pudieran afectar a la estructura, lo que por ende nos genera una ventaja de no amplificar parámetros

innecesarios, derivando de esta manera a resultados y gastos más aproximados.

Es importante enfatizar que de obviar este método de diseño, y optar por otro (Esfuerzos permisibles) el proyecto se tornaría sobre reforzado.

1.2.4. IMPORTANCIA:

Este trabajo de investigación muestra su importancia a manera de guía, ya que sugiere los procedimientos adecuados para diseñar las estructuras de acero por el método de los estados límites; estos procedimientos son detallados y ordenados de manera que sean comprensibles.

1.2.5. OBJETIVOS:

GENERAL

- Realizar el análisis y diseño de un edificio de acero por el método de los estados límites.

ESPECÍFICOS

- Calcular los esfuerzos y deformaciones de un sistema estructural de acero.
- Diseñar los elementos estructurales por el método de los estados límites.
- Detallar en planos CAD los resultados del diseño.

1.2.6. HIPÓTESIS:

Si se aplican los procedimientos adecuados que involucra el método de los estados límites en el análisis y cálculo de los elementos componentes de un edificio metálico; entonces se tendrá como resultado, un diseño final óptimamente estructurado que servirá como guía y ejemplo para futuros proyectos basados en sistemas de acero.

1.2.7. ESTRATEGIAS DE ESTUDIO:

1.2.7.1. MÉTODO DE ESTUDIO:

En el presente trabajo se aplicarán los criterios y los factores que intervienen el análisis y diseño recomendados por el método LRFD.

1.2.8. UNIDAD DE ANÁLISIS:

El edificio de acero estructural.

1.2.9. VARIABLES:

Variable Independiente

- El método de los estados límites.

Variable Dependiente

- Optimización de en los elementos estructurales.

1.2.10. DISEÑO DEL ESTUDIO:

El diseño del estudio es Explicativo.

1.2.11. TÉCNICAS E INSTRUMENTOS DE RECOLECCIÓN DE DATOS

Consultas en foros de internet.

1.2.12. TÉCNICAS DE PROCESAMIENTO DE DATOS INTERPRETACIÓN Y RESULTADOS DE ANÁLISIS

Uso de normas

Uso de libros

Uso de publicaciones

Uso de revistas

CAPITULO II

MARCO TEÓRICO

2.1.- FUNDAMENTOS EN EL DISEÑO ESTRUCTURAL

2.1.1.- ENTORNO AL DISEÑO ESTRUCTURAL

Entorno al diseño estructural hay diversas actividades que tiene que desarrollar el proyectista para definir la forma, dimensión y características detalladas de una estructura, estas son las partes de la construcción que tienen la capacidad de absorber las solicitudes que se presentan durante las distintas etapas de su existencia.

Un requisito esencial para que la construcción cumpla sus funciones o capacidades, es que no sufra fallas ni tenga mal comportamiento debido a su incapacidad para soportar las cargas que sobre ella se impongan. Además deben cuidarse otros aspectos, como los relacionados al funcionamiento, entre ellos tenemos las dimensiones mínimas, iluminación, ventilación, ascensores, escaleras, corredores, aire acondicionado, estética, cuidado ambiental y social, etc. que son temas a discutir con el cliente y otros profesionales que estén relacionados con la construcción; en particular el ingeniero estructural no debe olvidarse de que la obra no se construye solo para que resista, aunque es una condición fundamental, pero no la finalidad única, ni si quiera la primaria, ya que tenemos que tener en cuenta que va hacer habitada por una persona o conjunto de personas.

La construcción de este edificio de acero puede considerarse como un sistema, entendiéndose por un sistema un

conjunto de subsistemas y elementos que se combinan en forma ordenada para cumplir con determinada función. Tomando de ejemplo un edificio de acero, está integrado por varios subsistemas entre ellos el de los elementos arquitectónicos, estructural, instalaciones eléctricas, instalaciones sanitarias, el aire acondicionado y los elevadores.

Los sistemas nombrados interactúan de modo que en el diseño debe tenerse en cuenta la relación que existe entre ellos, no como se hace comúnmente en la práctica en nuestra localidad, en la cual el diseño de un edificio suele hacerse por la superposición sucesiva de los proyectos de los diversos subsistemas que lo integran, el arquitecto propone el proyecto sin tomar en cuenta los problemas estructurales, y el ingeniero estructural tiene que limitarse y adaptarse lo mejor posible a los requisitos arquitectónicos, lo cual muchas veces perjudica la resistencias de la estructura en si.

Algo que se observa también en nuestra localidad en el entorno estructural es que en las instalaciones muchas veces no se contrata a un especialista y el ingeniero civil es el que se encarga de plantear las soluciones, lamentablemente a veces de una manera inadecuada, perjudicando el buen funcionamiento de la edificación ya terminada.

Algo que no debe dejarse de recalcar en nuestro medio, las constructoras para poder ganar una licitación, muchas veces reducen el presupuesto, trayendo como consecuencia modificaciones importantes en las características arquitectónicas y estructurales; además haciendo esto, se ven en la necesidad de optar por el empleo de un proceso constructivo, que representa claras ventajas en costo y tiempo, pero que no se adapta al proyecto elaborado; trayendo consigo que se realicen adaptaciones apresuradas por los plazos de entrega ya muy cortos.

Los principios y fundamentos de diseño estructural que rigen a una moto, un automóvil, un tren, una mesa o un puente soportan diversas cargas para cumplir apropiadamente, sus funciones. La mecánica y resistencia de materiales son bases teóricas comunes que rigen la seguridad de todos esos sistemas. Aquí nos referimos solo a las estructuras de la construcción que entran en el ámbito de la ingeniería civil; entre estas tenemos a los puentes, represas, estructuras portuarias y marítimas y edificaciones, recordando que este trabajo está enfocado en edificaciones de acero.

2.1.2.- PROCESOS DEL DISEÑO ESTRUCTURAL

Lo que se conoce como diseño estructural "es una mezcla de arte y ciencia que combinan los sentimientos intuitivos del ingeniero con la Estática, Dinámica, mecánica de los

materiales y el Análisis estructural, para producir una estructura segura que sirva sus propósitos"

Tenemos que las soluciones estructurales están sujetas a las restricciones que surgen de la interacción con otros aspectos del proyecto y las limitaciones de costo y tiempo de ejecución.

El criterio intuitivo y cualitativo que se tuvo a un inicio va a tener, en ingeniería estructural, un significado más preciso entre los cuales se va a detallar:

- ✓ Costo Mínimo.
- ✓ Peso mínimo.
- ✓ Tiempo de ejecución mínimo.
- ✓ Trabajo mínimo.
- ✓ Máxima eficiencia operativa para el cliente.

En el Perú el peso mínimo es el criterio más usado.

Además vamos a considerar tres aspectos fundamentales del diseño, entre los cuales esta: la estructuración, el análisis y el dimensionamiento

Estructuración: En esta etapa del proceso se determina los materiales de los cuales va estar constituida la estructura, la forma global de esta el arreglo de los elementos y sus dimensiones y características más esenciales, es esta la parte fundamental del proceso. De la correcta elección del sistema

depende la buena calidad de los resultados; además es en esta parte donde entra a tallar la creatividad y el buen criterio.

Análisis: Es el conjunto de actividades que determinan la respuesta estructural ante las diferentes acciones exteriores que pueden dañar la edificación. Entre otras palabras se trata de determinar los efectos de las cargas que pueden afectar a la estructura durante su vida útil. Para esta determinación se requiere lo siguiente.

a) Modelar la estructura

Es idealizar la estructura real mediante un modelo teórico factible que debe ser analizado con los procedimientos de cálculos disponibles; como por ejemplo la idealización de un edificio en el cual las vigas, columnas y losas mediante el uso de un sistema de marcos planos formados por barra de propiedades equivalentes. En esta idealización se cometen con frecuencia errores graves, tales como ignorar elementos que constituyen a la respuesta de la estructura o emplear un modelo demasiado simplista que no representa adecuadamente la respuesta estructural. La modelación incluye la definición de diversas propiedades de los elementos que componen al modelo. Esto implica la recolección de diversos datos y la suposición de otras características, como son las propiedades elásticas de los materiales, incluyendo el suelo de la cimentación, y las propiedades geométricas de las distintas secciones.

Los valores puestos en las etapas iniciales del proceso para estas propiedades, pueden tener que modificarse e irse refinando a medida que se obtienen los resultados de análisis.

b) Determinar las acciones de diseño

Las cargas que introducen esfuerzos en la estructura están definidas en nuestro país en el Reglamento Nacional de Edificaciones en la Norma de Cargas(E0-20),en el cual se especifican las cargas estáticas mínimas que se deben adoptar para el diseño estructural; asimismo se proporciona las cargas estáticas equivalentes producidas por el viento, mientras que las cargas por sismo se especifican en la Norma de Diseño Sismo-Resistente (E0-30), estas cargas se denominan **cargas de servicio** ya que son las que realmente actúan el en edificio sin producir fallas o fisuras visibles, a diferencias de las **cargas ultimas** que son cargas ficticias obtenidas al multiplicar por ciertos factores las **cargas de servicio**, con un objetivo de diseñar en condición de **rotura** a los diferentes elementos estructurales. En esta etapa se llega a tener grandes incertidumbres y errores.

c) Determinar los efectos

Se determina los efectos de las acciones de diseño en el modelo de la estructura elegida; en esta etapa se determina las fuerzas internas (momento flexionante y de torsión, fuerzas

axiales y cortantes), así como las flechas y deformaciones de la estructura. Los métodos de análisis suponen en general un comportamiento elástico lineal. El desarrollo de los métodos numéricos asociado al empleo de las computadoras ha dado la posibilidad al ingeniero estructurista de analizar modelos estructurales cada vez más complejos.

Dimensionamiento

Se revisa con detalle la estructura y se observa si cumple con los requisitos de seguridad adoptados. Se elaboran planos, maquetas o métodos de izaje, también se requiere la elaboración de planos de fabricación, que son en aquellos en que se detalla cada miembro para que sean preparado en los talleres, así como todas las conexiones.

El proceso real es mucho más complejo e iterativo: implica pasar por varias veces por cada etapa a medida que la estructura evoluciona hacia su forma final.

El análisis de la secuencia temporal con que se realiza el diseño de una estructura permite distinguir las siguientes etapas:

a) Planeamiento:

Se establecen las condiciones funcionales a las que la estructura va a servir. Así que se define el criterio óptimo

b) Evolución de las soluciones preliminares.

En esta etapa es importante el ingenio y la experiencia del diseñador, se fija disposiciones de los miembros y tamaños iniciales para ser discutidos con el cliente y los otros profesionales.

c) Determinación de las cargas.

Tenemos que en esta etapa se estima las cargas, pero mientras se itera se va teniendo más precisión.

d) Selección preliminar de los miembros estructurales.

Se selecciona los miembros estructurales de tal manera que nos permita iniciar un análisis estructural en la siguiente etapa.

e) Análisis estructural

En esta etapa se crea el modelo matemático más adecuado a la realidad del verdadero comportamiento estructural de la edificación. Además se aplican los métodos de la mecánica para determinar los momentos flexionante y torsional, axiales y cortante, así como la flechas y deformaciones que tendrán los miembros estructurales, con el objetivo de poder compararlos con la resistencia que deberán tener dichos miembros, cosa que se va a efectuar en el siguiente paso.

f) Evaluación

En esta etapa se debe de preguntar si la resistencia o las condiciones de servicio que se obtienen mediante un reglamento superan a los resultados de la etapa previa. Si hay un margen de seguridad adecuado y económico se puede dar por concluido el diseño; si no fuera así pasar a la siguiente etapa.

g) Rediseño

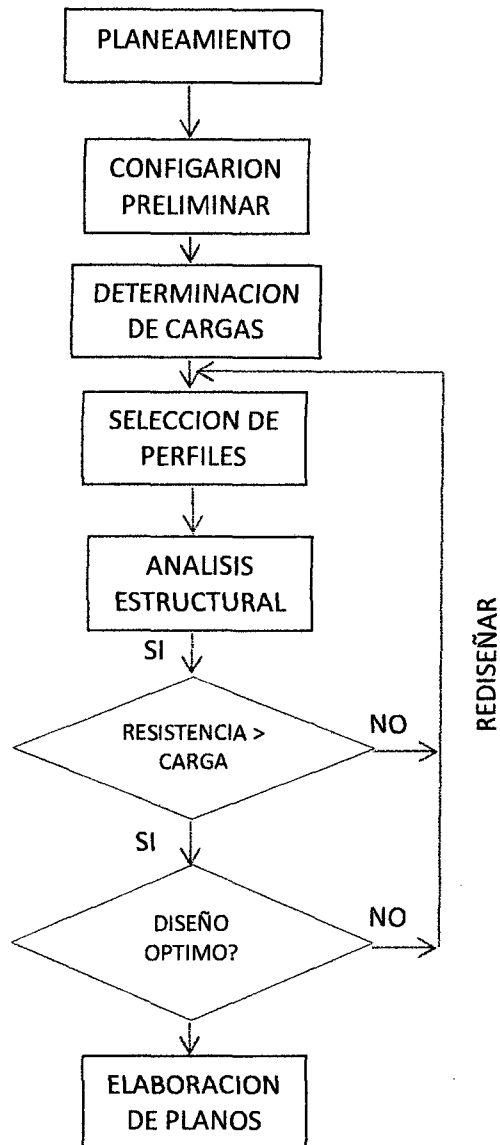

En este paso repetimos los pasos **c** y **f** para lograr cumplir los objetivos, esto se hace mediante un proceso iterativo.

h) Decisión

En esta etapa solo nos queda decidir si es que se ha logrado el óptimo buscado en un diseño. Si en esta etapa se cree que se ha logrado, entonces se da por concluido el proceso iterativo.

i) Elaboración de los planos de diseño y las especificaciones de trabajo correspondientes

Se tiene que presentar maquetas o planos de métodos de izaje, en otros casos se requiere la elaboración de los así llamados planos de fabricación.

2.1.3.- HERRAMIENTAS DE DISEÑO

Viendo en la historia, la aplicación de métodos cuantitativos al diseño es realmente reciente, aproximadamente más de un siglo que se está diseñando estructuras cuidando en forma más o menos completa los esfuerzos en sus miembros, en puentes de grandes claros fue en donde se huso por primera vez.

Como ejemplo tenemos la teoría usada actualmente para el dimensionamiento de columnas, incluyendo los efectos de pandeo, se basa con pocas adaptaciones, en la solución teórica desarrollada por Leonhard Euler hacia mediados del siglo XVII, no fue sino hasta después de un siglo que se dio a la teoría de Euler aplicación en el diseño estructural.

Antiguamente las estructuras se proyectaban con bases exclusivamente empíricas, a partir de la extrapolación de estructuras ya existentes y la intuición.

Tenemos como primeros intentos de sistematización del diseño los establecimientos de reglas geométricas que debían observarse para materiales y elementos construidos dados, con el objetivo de asegurar su estabilidad, muchas de esas reglas fueron recopiladas por Vitrubio en el primer siglo; fueron de uso común hasta el renacimiento, cuando la popularización del método experimental condujo a procesos más refinados.

El procedimiento empírico tiene bastantes limitaciones de que es confiable solo si se trata de estructuras esencialmente similares a otras ya existentes y comprobadas, resultan muy peligrosos extrapolar la experiencia a condiciones diferentes a las previas; para algunas personas no se justifica el

empleo de los métodos de diseño, dado que sin ellas se puede realizar estructuras tremendas que han dura siglos de siglos, bastando para ello solamente la intuición, el buen sentido estructural y la experiencia del comportamiento de estructuras previas, pero como se explico es muy limitada.

El proyectista cuenta actualmente para apoyar su intuición con tres tipos de ayuda:

✓ Método analítico.

Este método ha tenido un desarrollo en las últimas décadas extraordinario, el cual toma en cuenta los efectos de la no linealidad del comportamiento de los materiales, la interacciona de la estructura con el suelo y el comportamiento dinámico, hay que tener siempre en cuenta que lo que analizan estos métodos son modelos o idealizaciones matemáticas tanto de la estructura misma, como de las acciones a las que está sujeta y los materiales que lo componen, hay un grave peligro en los proyectistas poco experimentados con este procedimiento de análisis muy refinado, puede que pierda el sentido físico del problema que está resolviendo y no sepa juzgar si los resultados obtenidos son realista o no.

✓ Los manuales y normas.

Se tiene que de la experiencia de la solución analítica de un gran número de problemas, del comportamiento de una estructura, por ejemplo en los sismos, nos ha enseñado su comportamiento real en ese campo, y de las investigaciones realizadas, se obtenido manuales y normas o reglamentos como el caso de nuestro país, aunque somos solo copiadorees en mucho de los casos de las normas de otros países.

Se debe de tener cuidado, con en el uso indiscriminado de esta herramienta; el proyectista debe de tener el buen juicio para determinar si su caso particular cumple con la hipótesis y limitaciones con que se elabora las tablas, graficas o especificaciones generales.

Tenemos unos mandamientos para los proyectistas cuando utiliza las herramientas de manuales, tablas y especificaciones generales:

- Nunca hagas usos de estas herramientas si no sabes a cabalidad la teoría en la cual se basa, que hipótesis tiene implícitas y cuáles son las límites para su uso

- Observa si para el caso en particular que estás viendo es aplicable, ten cuidado hacer uso de las unidades y obtén los datos que se requieren para su empleo.
- Si ya has obtenido los resultados, utiliza el criterio minuciosamente, mira si es que tiene sentido lo que has obtenido, y si aun tienes dudas compruébalo nuevamente con otros procedimientos.
- Piensa que aspectos no han sido tomados y asegúrate que no cambien ni alteren el diseño.

✓ La experimentación

Esta herramienta hace el huso de modelos físicos, estos te llevan a diversos niveles. Resulta muy útil en ocasiones para entender un aspecto parcial de cómo responde una estructura ante determinado tipo de carga, no se trata de obtener determinaciones cuantitativas de la respuesta, si no de logara una representación física de la manera física en la que se deforma la estructura.

Una manera ya mucho más completa es través de ensayar un modelo a escala de la

estructura o de parte de ella. Se tiene que las dimensiones y las propiedades de los materiales y las cargas en el modelo se deduce mediante la teoría del análisis dimensional. Este método tiene la ventaja de permitir una observación objetiva y física del fenómeno, se tiene que la necesidad de reducir la escala del modelo con respecto a la estructura real lleva, por los requisitos de análisis dimensional, el empleo de materiales que tienen propiedades mecánicas distintas con el modelo real, por lo cual es difícil representar el comportamiento de la estructura más allá del intervalo inicial lineal, la dificultad de reproducir la estructura en lo más mínimo de sus detalles influyen en la respuesta estructural.

Estas herramientas no remplazan al proceso creativo, el razonamiento lógico y el examen crítico del problema ya que no es la esencia del diseño mismo.

2.1.4.- ESTADOS LÍMITES

Las estructuras deben cumplir, entre otros, los requisitos de Estabilidad, Resistencia, Funcionalidad y Durabilidad. El procedimiento utilizado para garantizar que se

cumplen estos requisitos con una adecuada fiabilidad o, dicho de otro modo, con una probabilidad suficientemente pequeña, es el Método de los Estados Límite.

Si la estructura supera alguno de los Estados Límite se puede considerar que esta ya no cumple las funciones para las que ha sido proyectada.

Dicho método diferencia los Estados Límite Últimos o Falla y los Estados Límite de Servicio agrupando la resistencia y la estabilidad como Últimos y los funcionales como de Servicio. Tenemos que los Estados Límite Últimos están relacionados con la rotura y los de Servicio con la utilización

2.1.4.1. ESTADOS LÍMITES ÚLTIMOS

Estado Límite Último (ELU) es un estado límite, tal que de ser rebasado la estructura completa o una parte de la misma puede colapsar al superar su capacidad resistente. En general el que un ELU sea sobrepasado es una situación extremadamente grave, que puede provocar cuantiosos daños materiales y desgracias personales. Por esa razón los coeficientes de seguridad usados en los cálculos relacionados con un ELU son substancialmente mayores que en otro tipo de estados límite.

2.1.4.2. ESTADOS LÍMITES DE SERVICIO

Un Estado Límite de Servicio (ELS) es un tipo de estado límite que, de ser rebasado, produce una pérdida de funcionalidad o deterioro de la estructura, pero no un

riesgo inminente a corto plazo. En general, los ELS se refieren a situaciones solventables, reparables o que admiten medidas paliativas o molestias no-graves a los usuarios. El que un ELS sea rebasado no reviste la misma gravedad que el que un ELU se sobrepasado. En los cálculos de comprobación de los ELS se emplean márgenes de seguridad más moderados que en los ELU.

Ejemplos De Estados Límites

Algunos de los Estados Límites típicos son:

Estados Límite Últimos (ELU)

- ✓ ELU de agotamiento por sollicitación normal (flexión, tracción, compresión)
- ✓ ELU de agotamiento por sollicitación tangente (cortadura, torsión).
- ✓ ELU de inestabilidad elástica (Pandeo, etc.)
- ✓ ELU de equilibrio (equilibrio mecánico: vuelco, deslizamiento, etc.).

Estados Límite de Servicio (ELS)

- ✓ ELS de deformación excesiva.
- ✓ ELS de vibración excesiva.
- ✓ ELS de fisuración excesiva.
- ✓ ELS de durabilidad (oxidación, fisuración, etc.)

2.1.5.- CARGAS DE DISEÑO

En el diseño de un edificio es necesario determinar las cargas que ha de soportar el esqueleto o estructura del edificio. Estas cargas se dividen en cargas muertas, cargas vivas, de sismo y de viento.

2.1.5.1.- TIPOS DE CARGAS

En general, las cargas (o solicitaciones) que pueden actuar en un edificio clasifican en los siguientes tipos: Cargas Estáticas, Cargas Dinámicas y Otras Solicitaciones.

2.1.5.1.1.- Cargas Estáticas.

Son aquellas que se aplican lentamente sobre la estructura, lo cual hace que se originen esfuerzos y deformaciones que alcanzan sus valores máximos en conjunto con la carga máxima.

Prácticamente, estas solicitaciones no producen vibraciones en la estructura, ya su vez clasifican en:

a) Cargas Permanentes o Muertas.

Son cargas gravitacionales que actúan durante la vida útil de la estructura, como por ejemplo: el peso propio de la estructura y el peso de los elementos añadidos a la estructura (acabados, tabiques, maquinarias para ascensores y cualquier

otro dispositivo de servicio que quede fijo en la estructura).

b) Carga Viva o Sobrecarga.

Son cargas gravitacionales de carácter movable, que podrían actuar en forma esporádica sobre los ambientes del edificio. Entre estas solicitaciones se tiene: al peso de los ocupantes, muebles, nieve, agua, equipos removibles, puente grúa, etc. Las magnitudes de estas cargas dependen del uso al cual se destinen los ambientes.

2.1.5.1.2.- Cargas Dinámicas.

Son aquellas cuya magnitud, dirección y sentido varían rápidamente con el tiempo, por lo que los esfuerzos y desplazamientos que originan sobre la estructura, también cambian con el tiempo; cabe indicar que el instante en que ocurre la máxima respuesta estructural, no necesariamente coincide con el de la máxima sollicitación Estas cargas clasifican en:

a) Vibraciones Causadas por Maquinarias.

Cuando las máquinas vibratorias no han sido aisladas de la estructura principal, sus vibraciones pueden afectar tanto a la estructura que las soporta como a las estructuras vecinas.

b) Viento.

El viento es un fluido en movimiento; sin embargo, para simplificar el diseño, se supone que actúa como una carga estática sobre las estructuras convencionales, pero, para estructuras muy flexibles (puentes colgantes, chimeneas, etc.) es necesario verificar que su período natural de vibrar no coincida con el de las ráfagas de viento, de lo contrario, podría ocurrir la resonancia de la estructura.

FIGURA No 2.1: Viento

Fuente: Libro Zapata Baglietto

c) Sismos.

Las ondas sísmicas generan aceleraciones en las masas de la estructura y por lo tanto, fuerzas de inercia que varían a lo largo del tiempo; sin embargo, las estructuras convencionales pueden ser

analizadas empleando cargas estáticas equivalentes
a las producidas por el sismo.

FIGURA No 2.2:Sismos

Fuente: Libro Zapata Baglietto

d) Cargas Impulsivas.

Son aquellas que tienen corta duración (dt),
por ejemplo: las explosiones.

2.1.6.- RESISTENCIA DE DISEÑO

El Método de Diseño por Resistencia provee un determinado margen de seguridad estructural mediante dos recursos:

1. Disminuye la resistencia nominal mediante el uso de un factor de reducción de la resistencia ϕ .
2. Aumenta la resistencia requerida usando cargas o sollicitaciones mayores.

Este criterio se materializa en el Reglamento exigiendo que en todas las secciones se cumpla la siguiente inecuación:

$$\text{Resistencia de Diseño} \geq \text{Resistencia Requerida}$$

Dónde:

Resistencia de Diseño = Factor de Reducción de la Resistencia (ϕ) \times Resistencia Nominal.

Resistencia Requerida = Σ (Factores de carga \times Solicitaciones provocadas por un estado de cargas de servicio).

Siendo:

Factor ϕ : Factor menor que la unidad que reduce la resistencia para considerarlas incertidumbres en los materiales y en las dimensiones.

Resistencia Nominal: Resistencia de un elemento o de una sección transversal antes de aplicar cualquier factor de reducción de la resistencia.

Factor de Carga: Factor que incrementa la carga para considerar las incertidumbres en la variación de las cargas de servicio.

Carga de Servicio: Carga especificada por el Reglamento Nacional De Edificaciones (E0-20) correspondiente (no mayores).

RESISTENCIA NOMINAL VS. RESISTENCIA DE DISEÑO

Las reglas para el cálculo de la **resistencia nominal** se basan en los estados límites establecidos para tensión, deformación, fisuración o aplastamiento, y concuerdan con resultados experimentales para cada tipo de acción estructural. La resistencia nominal se evalúa asumiendo que la sección tendrá exactamente las dimensiones y las propiedades de los materiales supuestas en los cálculos.

La **resistencia de diseño** proporcionada por un elemento estructural, sus uniones con otros elementos y su sección transversal, es igual a la resistencia nominal calculada de acuerdo con las ecuaciones e hipótesis estipuladas en el Reglamento, multiplicada por un factor de reducción de la resistencia ϕ .

2.2.- DISEÑO ESTRUCTURAL DE ACERO

2.2.1.- VENTAJAS DEL ACERO COMO MATERIAL ESTRUCTURAL

En nuestro país podemos observar, que el acero se utiliza en puentes, torres de transmisión, y en techos como tijerales para grandes luces, y en otras estructuras de este material.

El acero por su parte, durante los últimos tiempos de desarrollo ha logrado incrementar su consumo y su uso, esto se debe a las características las cuales le permiten ser un material óptimo para la construcción, ya que el acero es la resultado de la aleación del hierro, carbono y pequeñas cantidades de otros elementos como silicio, fósforo, azufre y oxígeno que le tributan características específicas.

El acero laminado en caliente, fabricado con fines estructurales, se denomina como acero estructural al carbono, con límite de fluencia de doscientos cincuenta (250) mega pázcales (2•549 Kg. /cm²).

El acero puede laminarse económicamente en una variedad y formas de tamaño sin un cambio apreciable de sus propiedades físicas.

Ventajas Del Acero Como Material De Construcción

a) **Alta Resistencia.**-La alta resistencia del acero por unidad de peso implica que será poco el peso de las estructuras, esto es de gran importancia, en el diseño de vigas de grandes

claros, como en puentes, en edificios altos y en edificios con condiciones deficientes en la cimentación, como en Chimbote.

b) Uniformidad.-Las propiedades del acero no cambian apreciablemente con el tiempo como es el caso de las estructuras de concreto reforzado.

c) Durabilidad.-Si el mantenimiento de las estructuras de acero es adecuado duraran indefinidamente.

d) Ductilidad.-La ductilidad es la propiedad que tiene un material de soportar grandes deformaciones sin fallar bajo altos esfuerzos de tensión. La naturaleza dúctil de los aceros estructurales comunes les permite fluir localmente, evitando así fallas prematuras, una ventaja adicional de las estructuras dúctiles, es que, al sobre cargarlas, sus grandes deflexiones ofrece evidencia visible de la inminencia de la falla.

e) Tenacidad.-Los aceros estructurales son tenaces, es decir, poseen resistencia y ductilidad, esta característica es muy importante porque implica que los miembros de acero pueden someterse a grandes deformaciones durante su formación y montaje, sin fracturarse, siendo posible doblarlos, martillarlos y taladrarlos sin daño aparente. La propiedad de un material para absorber energía en grandes cantidades se denomina tenacidad.

Propiedades Diversas.-otras ventajas del acero estructural son:

a) **Estética y Creatividad.**-El acero, por su ligereza, alta resistencia y elasticidad, ha permitido a los arquitectos llevar a la práctica sorprendentes ideas que anteriormente eran imposibles de realizar. El resultado han sido obras de diseño innovador y de gran libertad creativa, que destacan por sus formas elásticas y su enorme ligereza, disfrutan de iluminación natural y ofrecen inmensos espacios libres de columnas.

FIGURA N° 2.3: Estética y creatividad

Fuente:http://www.elmundo.es/albumes/2008/04/18/estadio_olimpico/index_10.htm

b) **Flexibilidad.**- Con frecuencia los propietarios de los edificios han de modificar un espacio ya existente (añadir una nueva fachada, una escalera o un nuevo elemento arquitectónico, elevar o rebajar el techo) para adaptarlo a nuevas necesidades y actividades.

FIGURA N° 2.4: Flexibilidad

Fuente: Mabani Steel

c) **Precisión.-** Las complejas y creativas formas con que nos sorprenden algunas de las más recientes construcciones metálicas, como puentes, estadios, pabellones y museos, sólo han podido lograrse gracias a la altísima precisión y exactitud que ofrecen las nuevas tecnologías informáticas.

Los programas de diseño asistido por ordenador permiten elaborar rápidamente layouts de las obras, realizar análisis y diseños con gran precisión, y crear secciones especiales de acero con ángulos y características inusuales.

FIGURA N° 2.5: Precisión

Fuente: <http://spanish.peopledaily.com.cn/31615/6439156.html>

d) Facilidad Y Rapidez De Montaje.- En una obra, la velocidad de construcción puede ser vital para el cliente. Además, el acero se encuentra disponible en perfiles en gran cantidad de tamaños y formas, lo que optimiza su uso y simplifica el montaje.

FIGURA N° 2.6: Facilidad y Rapidez de Montaje

Fuente: <http://www.hotfrog.com.pe/Empresas/ALEMFER-C-G-SAC/ESTRUCTURAS-METALICAS-66>

Esto hace posible que la mayor parte de una estructura se pueda prefabricar en el taller, y de esta manera se logra una mayor exactitud y precisión.

- e) **Economía.**-La construcción en acero supone una importante reducción de los costos, especialmente porque las estructuras son ligeras y más resistentes, lo que permite cimientos menos profundos, y porque el montaje resulta muy rápido y eficaz. Pero también por otras razones: en una construcción metálica, las conducciones y tuberías pueden pasar a través de las aberturas de las vigas en vez de hacerlo a través de una capa independiente por encima o por debajo del suelo, lo que reduce el peso de la estructura y los costes finales. Además, las estructuras metálicas ofrecen una gran durabilidad, gracias

a su alta resistencia a la corrosión y a su facilidad de mantenimiento.

- f) **Seguridad.**- Las estructuras metálicas son altamente resistentes a extremas situaciones de carga, como los terremotos o huracanes, y al fuego. El acero posee una excepcional ductilidad y tenacidad, por lo que puede soportar importantes deformaciones sin que la integridad del edificio resulte perjudicada. Sus propiedades no se alteran con el paso del tiempo ni varían con la localización en los elementos estructurales. Los cuidadosos controles de calidad a que se someten los materiales aseguran unos resultados altamente satisfactorios.

FIGURA N° 2.7: Seguridad

Fuente: <http://spanish.alibaba.com/product-gs/metal-buildings-steel-construction-factory-steel-building-204980313.html>

- g) **Ecología.**-El acero es un material reciclable al 100%. La mitad la producción anual de acero del mundo procede de acero

reciclable, lo que asciende a 400 millones de toneladas. De esta forma, el acero utilizado constituye materia prima, material no desechable y que no contamina, y puede ser reciclado varias veces sin perder por ello la calidad.

2.2.2. DESVENTAJAS DEL ACERO COMO MATERIAL ESTRUCTURAL

a) Costos de Mantenimiento.-La mayor parte de los aceros son susceptibles a la corrosión al estar expuestos al agua y al aire y, por consiguiente, deben pintarse periódicamente.

b) Costos de la protección contra el fuego.-Aunque algunos miembros estructurales son incombustibles, sus resistencias se reducen considerablemente durante los incendios. Además se ha comprobado que por su gran capacidad de conducir calor ha provocado la propagación de incendios, elevando la temperatura de habitaciones donde no hay flamas o chispas de ignición más por el alto calor conducido ha logrado inflamar otros materiales usuales como madera, tela y otros.

c) Susceptibilidad al pandeo.- Es decir entre más esbeltos sean los miembros a compresión, mayor es el peligro de pandeo. Como se indicó previamente, el acero tiene una alta resistencia por unidad de peso, pero al utilizarse como columnas no resulta muy económico ya que debe usarse bastante material, solo para hacer más rígidas las columnas contra el posible pandeo. Sin embargo

cabe la posibilidad de usar perfiles que tengan dentro sus propiedades grandes momentos de inercia abundando a mitigar esta desventaja.

d) Fatiga.-Otra característica inconveniente del acero es que puede su resistencia puede reducirse si somete a un gran número de inversiones del sentido de esfuerzo, o bien a un gran número de cambio de la magnitud del esfuerzo de tensión (solo se tendrá el problema de fatiga cuando se presenta tensiones).

f) Fractura frágil.- Bajo ciertas condiciones, el acero puede perder su ductilidad y la falla frágil puede ocurrir en lugares de concentración de esfuerzos. Las cargas que producen fatiga y muy baja temperatura agrava la situación.

2.2.3.- PRIMEROS USOS DEL HIERRO Y ACERO

Hierro: Elemento químico natural y metálico de gran resistencia mecánica (Fe).

3000 a. C. Se emplean ya utensilios tales como herramientas y adornos hechos de "acero" en el antiguo Egipto. Se encuentran dagas y brazaletes de hierro en la pirámide de Keops con más de 5000 años de antigüedad.

1000 a. C. Inicio de la edad del hierro, primeros indicios en su fabricación se cree que un incendio forestal en el monte Ide de la antigua Troya (actual Turquía) fundió depósitos ferrosos produciendo hierro. Otros creen que se comenzó a emplear a

partir de fragmentos de meteoritos donde el hierro aparece en aleación con Níquel.

490 a. C. Batalla de Maratón Grecia. Los atenienses vencen con sus armas de hierro a los persas, que aún emplean el bronce, con un balance de 6400 contra 192 muertos.

Acero: aleación de hierro (99 %) y carbono (1 %) y de otros elementos de la más alta resistencia mecánica.

1000 a. C. Se cree que el primer acero se fabricó por accidente al calentar hierro con carbón vegetal siendo este último absorbido por la capa exterior de hierro que al ser martillado produjo una capa endurecida de acero. De esta forma se llevó a cabo la fabricación de armas tales como las espadas de Toledo y

1779 d. C. Se construye el puente Coalbrookdale de 30 m de claro, sobre el río sueon en Shropshire. Se dice que este puente cambia la historia de la revolución industrial, al introducir el hierro como material estructural, siendo el hierro 4 veces más resistente que la piedra y 30 veces más que la madera.

1819 Se fabrican los primeros ángulos laminados de hierro en E.U.A.

1840 El hierro dulce más maleable, comienza a desplazar al hierro fundido en el laminado de perfiles.

1848 Willian Kelly fabrica acero con el proceso Bessenor en E.U.A.

1855 Henry Bessenor consigue una patente inglesa para la fabricación de acero en grandes cantidades Kelly y Bessenor observan que un chorro de aire a través del hierro fundido quema

las impurezas del metal, pero también eliminaba el carbono y magnesio, además el acero comenzó a desplazar el hierro forjado y el hierro colado en la construcción.

1870 con el proceso Bessenor se fabrican grandes cantidades de acero al bajo carbono.

1874 En Estados Unidos, el primer puente ferroviario de acero estructural fue el puente Eads, construido en St. Louis; Missouri.

1884 se terminan las primeras vigas IE (I estándar) de acero en E.U.A. fue terminado en Chicago el primer edificio con estructura de acero. William Le Baron Jerry diseña el primer "rascacielos" (10 niveles) con columnas de acero recubiertas de ladrillo. Las vigas de los seis pisos inferiores se fabrican en hierro forjado, mientras que las de los pisos restantes se fabrican en acero.

1889 se construye la torre Eiffel de París, con 300m de altura, en hierro forjado, comienza el uso de elevadores para pasajeros operando mecánicamente.

2.2.4.- ACEROS ESTRUCTURALES

De todos los tipos de acero que se pueden producir, los que más interesan para la construcción son los Aceros Estructurales, adecuados para resistir esfuerzos.

En un mundo cada vez más interrelacionado es conveniente emplear designaciones de material de alcance internacional para poder aprovechar la potencia de los más recientes desarrollos, en especial cuando se presentan nuevos

conocimientos. Queda siempre al diseñador la obligación de utilizar el material nacional similar.

Las características que son de mayor relevancia para los ingenieros que quieran diseñar en acero, puede examinarse graficando los resultados de una prueba de tensión, si un espécimen de prueba es sometido a una carga axial P , como se muestra en la figura 2.6.

FIGURA N° 2.8: Curva Esfuerzo unitario vs. Deformación Unitaria

Fuente: Libro de Zapata Baglietto.

Punto de Fluencia: F_y , cuando se termina la proporcionalidad entre esfuerzos y deformaciones en un espécimen libre de esfuerzos residuales. Curva típica de un acero dúctil o acero dulce, la relación entre el esfuerzo y la deformación unitaria es lineal hasta el límite de proporcionalidad, se dice que el material obedece la ley de Hooke.

Resistencia a la fluencia: F_y , en ciertos aceros es necesario definir un concepto similar al anterior cuando no hay un

Punto preciso de fluencia. Ocurre con aceros de alta resistencia o con tratamiento en frío. Se acepta, un valor adecuado, Fig. 2.7.

FIGURA N° 2.9:

Fuente: Libro de Zapata Baglietto. -

Límite de Proporcionalidad: F_p , en ensayos con aceros no tratados térmicamente (recocido) y que son la mayoría, se observa que se pierde la proporcionalidad antes de llegar al Punto de Fluencia y ello se debe a la presencia de los llamados Esfuerzos Residuales que se generan en el elemento cuando éste se enfría luego de su laminado en caliente. Los esfuerzos residuales, que pueden ser de compresión o de tracción, se suman algebraicamente a los esfuerzos del ensayo y cambian el comportamiento esperado en el espécimen. Como hay estructuras que van a ser estudiadas en el rango elástico, es conveniente que se conozca el Límite de Proporcionalidad, así:

$F_p = F_y - 10 \text{ ksi}$ ($F_y - 705 \text{ kg/cm}^2$) para perfiles laminados en caliente,

$F_p = F_y - 16 \text{ ksi (} F_y - 1130 \text{ kg/cm}^2\text{)}$ para perfiles soldados.

Resistencia a la Fractura: F_u , el esfuerzo de falla del espécimen.

($F_u = 58 \text{ ksi}$ para Acero A36, $F_u = 4080 \text{ kg/cm}^2$).

Módulo de Elasticidad: E , la relación entre el esfuerzo y la deformación en el rango elástico. $E = 29,500 \text{ ksi (} 2100000 \text{ kg/cm}^2\text{)}$ para todos los aceros, cualquiera sea su Grado o aleación, por lo que se considera que es la característica que los agrupa y los diferencia apropiadamente.

Ductilidad: Propiedad del acero que permite que se deforme grandemente antes de fracturarse.

Módulo en la Zona de Endurecimiento por Deformación:

Es, aproximadamente 490000 Kg/cm^2 . Este endurecimiento final explica la resistencia encontrada en elementos de acero que han sobrepasado la zona plástica.

Relación de Poisson: $\mu = e_t/e_l$, se denomina a la relación entre la deformación transversal y la longitudinal del acero para un determinado rango de esfuerzos: $\mu = 0.3$. Se usa para definir el comportamiento de planchas cuando son sometidas a fuerzas de borde.

Módulo de Elasticidad en Corte: G, Relación entre el esfuerzo en corte aplicado y la deformación correspondiente en el rango elástico. De la teoría de elasticidad se conoce la siguiente relación:

$$G = E / [2(1+\mu)], G = 11,300 \text{ ksi (800000 kg/cm}^2\text{)}$$

para los aceros estructurales.

Tenacidad del acero: Capacidad para absorber energía y se mide por el área encerrada dentro de la curva Esfuerzo-Deformación.

Densidad específica del acero: 57.8

Soldabilidad: Capacidad del acero a ser soldado y depende de la composición química del material y es muy sensitiva al contenido del carbono en su masa. Hay aceros que no son soldables o difícilmente soldables, por lo que requieren un tratamiento especial.

Además del ensayo a la tracción que se ha mostrado, hay otros ensayos normalizados que permiten discernir la calidad del acero que se piensa usar y que brevemente se explican a continuación:

-
- **Ensayo de Doblado**, para averiguar la ductilidad del acero para el plegado de las planchas en la formación de perfiles livianos.

 - **Ensayo de Entalladura**, para conocer la fragilidad del material.

 - **Ensayo a la Fatiga**, que tiene por objeto conocer el comportamiento que tendrá del acero bajo cambios de cargas frecuentes.

2.2.4.1.- EFECTOS DE LA TEMPERATURA EN EL ACERO

2.2.4.1.1.- EFECTOS DE LAS ALTAS TEMPERATURAS

El acero no es un material inflamable; sin embargo, la resistencia depende en alto grado de la temperatura, la resistencia tanto de fluencia como de tensión es alrededor del 60 a 70 por ciento de la obtenida a la temperatura ambiente (alrededor de 70°F). La pérdida de resistencia es bastante notable a altas temperaturas, donde se ve que la resistencia a 600°F es sólo el 15 por ciento de la resistencia a la temperatura ambiente. Las estructuras de acero que encierren materiales inflamables requerirán protección contra incendios para controlar la temperatura del metal el tiempo suficiente para que los ocupantes lleguen a un lugar seguro o para que el fuego consuma los materiales combustibles o que se pueda apagar antes de que el

edificio se desplome. En muchos casos, el edificio no llega a desplomarse, aun a altas temperaturas; más bien, la deformación de los miembros sobrecalentados es demasiado grande para ser aceptable y dichos miembros deben ser removidos.

Se han establecido clasificaciones de protección contra incendios para los diversos materiales y espesores que se pueden aplicar a un miembro estructural para controlar la temperatura. Se incluyen productos a base de yeso, o concreto ligero que se puede rociar sobre el miembro o tableros aislantes de fibra para proteger el acero. Cuando el miembro de acero sea hueco, se puede proveer un líquido con un agente anticongelante, para el control de las altas temperaturas.

2.2.4.1.2.- EFECTOS DE LAS BAJAS TEMPERATURAS

La fractura frágil a menudo se asocia con las bajas temperaturas. Básicamente, la fractura frágil ocurre sin que haya fluencia del material. Las curvas de esfuerzo indican que en la falla usual de un espécimen a tensión, tiene lugar una considerable elongación. De hecho, en la prueba estándar tensión de la ASTM, se especifica un por ciento mínimo de elongación para el acero. En el diseño del acero está implícita la deformación resultante (fluencia) del material bajo un alto esfuerzo local. Cuando el material sufre elongación, las dimensiones laterales se contraen, debido al efecto de Poisson. Si las dimensiones

laterales están total, o hasta parcialmente restringidas, el acero se separará sin desarrollar totalmente su potencial de fluencia. Este tipo de falla constituye lo que se conoce como "fractura frágil". Tenemos que una muesca es un cambio abrupto en el área de la sección transversal- para inhibir la contracción lateral en una situación de tensión.

Una combinación de baja temperatura, un cambio en las dimensiones de la sección (efecto de muesca) o alguna imperfección, junto con la presencia de esfuerzos de tensión, pueden iniciar una fractura frágil. Esto puede empezar como una grieta que se desarrolla hasta constituir la falla de un miembro. No todos los miembros que presentan muescas en un ambiente de baja temperatura y sometido a una alta tasa de deformación por tensión fallan; tiene que haber exactamente la combinación apropiada de deformación y tasa de deformación, temperatura y efecto de muesca. Sin embargo, si ocurriese una falla catastrófica, el hecho de que haya muy poca probabilidad de que ocurra la combinación para la falla, ayudará bien poco para ajustar las demandas por daños que resultan de la falla y que es más que de seguro que se presentarán. La fractura frágil se puede controlar de varias maneras:

- Detállense los miembros y sus conexiones a fin de hacer mínimas las concentraciones de esfuerzos.

- Especifíquese la secuencia de fabricación y montaje para minimizar los efectos residuales de tensión.
Úsense aceros que tengan
- Úsense aleaciones especiales para emplearlos en ambientes de baja temperatura (véase ASTM A-633).
- Aplíquese un esfuerzo de pretensión preferiblemente a una temperatura elevada, o si no a temperatura normal a la zona de la muesca para generar una fluencia local antes de que se presenten las cargas de servicio y por temperatura.
- Si fuera posible, púlase la muesca para obtener una transición suave.
- Redúzcase la tasa de aplicación de la deformación a tensión.

2.2.4.1.3.- TRATAMIENTOS TÉRMICOS DEL ACERO

El tratamiento térmico del acero permite cambiar las propiedades del acero.

Se conocen tres tratamientos.

Templado, cuando el material se enfría rápidamente, se tiene un acero de un Punto de Fluencia alto pero de baja ductilidad.

Revenido, es otro proceso similar pero no tan rápido.

Recocido, en que se calienta el material en un horno hasta altas temperaturas, para después enfriarlo lentamente con el objeto de retirarle los esfuerzos residuales de la etapa de laminación o del proceso de soldadura.

2.2.4.1.4.-TRATAMIENTO MECÁNICO DEL ACERO

Cuando se aumenta el laminado de las planchas de acero se mejora la resistencia.

La explicación es que las moléculas se orientan en una sola dirección y su fuerza molecular tiene una única dirección. Lo mismo ocurre con el trefilado, cuando las varillas son alargadas en frío pasando huecos de menor diámetro hasta convertirse en hilos (para ser usados en cables) aumentando la resistencia o punto de Fluencia varias veces.

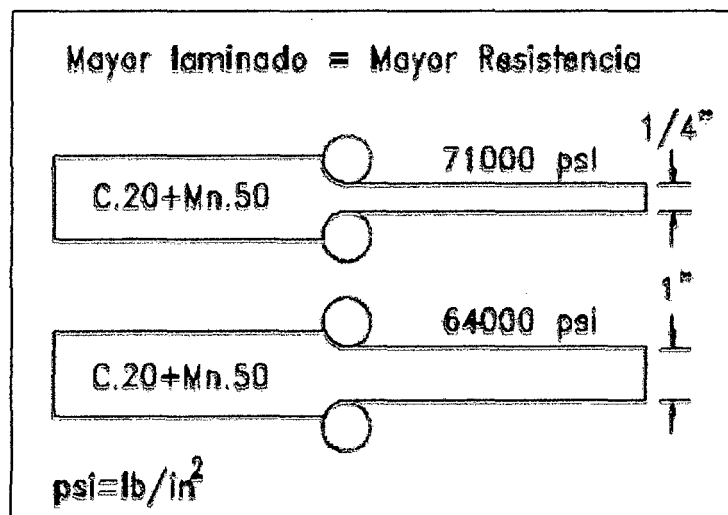

FIGURA N° 2.10: Tratamiento mecánico del acero

Fuente: Libro de Zapata Baglietto.

2.2.4.1.5.-COMPOSICIÓN QUÍMICA DEL ACERO Y SU INFLUENCIA EN LAS PROPIEDADES

Los aditivos más importantes del acero para muchas de sus propiedades mecánicas son el carbono y el manganeso.

Los siguientes elementos usados en aleaciones de acero proporcionan las siguientes características:

Cromo: Le da mayor resistencia a la corrosión, y al desgaste.

Cobre: Le da resistencia a la corrosión y la ductilidad del acero.

Manganeso: Presente en todos los aceros estructurales, mejora la resistencia, ductilidad e influye favorablemente en los tratamientos térmicos.

Molibdeno: Mejor resistencia a altas temperaturas y la resistencia a la corrosión.

Níquel: Impide la fragilidad en temperaturas bajas y mejora la resistencia a la corrosión.

Silicio: mejora la resistencia.

Los aceros estructurales pueden agruparse de acuerdo a su composición, como sigue:

Aceros Simples al Carbono.- Principalmente hierro y carbono, con menos de 1% de carbono.

Aceros de Baja Aleación.- Hierro y carbono y otros componentes (usualmente menos del 5%), los componentes adicionales son principalmente para incrementar la resistencia, que se logra a costa de una reducción de la ductilidad.

Aceros Especiales o de Alta Resistencia.- similares a los aceros de baja aleación pero con un mayor porcentaje de componentes agregados al hierro y el carbono. Esos aceros son de resistencia superior y resistencia a la corrosión.

Las Especificaciones ASTM (America Society for Testing and Materials) reconocen 14 Grados de Acero en total. Entre de los aceros al Carbono, el más conocido es el A36, y entre los aceros de Alta Resistencia, los aceros ASTM A242, A572 y A588. A continuación se da una Tabla con alguna de sus propiedades más significativas.

TABLA 2.1: Especificaciones ASTM.

Designación ASTM	F_y ksi (t/cm^2)	F_u ksi (t/cm^2)	Máximo espesor en planchas, in.	Uso en perfiles ASTM A5, grupos
A36	36(2.53)	58(4.08)	8	todos
A242	42	63	de 1.5 a 4	4,5
	46	67	de 3/4 a 1.5	3
	50	70	hasta 3/4	1,2
A572 Grado 42	42	63	hasta 6	todos
A572 Grado 50	50	65	hasta 4	todos
A572 Grado 60	60	75	hasta 1.25	1,2
A572 Grado 65	65	80	hasta 1.25	1

ksi: kip/in^2 t/cm^2 : toneladas/ cm^2

Fuente: Zapata Baglietto.

Usos de los aceros estructurales ASTM

- A36 Para propósitos generales en estructuras, especialmente de edificaciones, soldadas o empernadas.
- A242 Para puentes empernados o soldados, resistentes a la oxidación.
- A572 Para perfiles estructurales, planchas, y barras para edificaciones empernadas o soldadas; puentes soldados sólo en los Grados 42 y 50.

2.2.5. Aceros Estructurales en El Perú

Son producidos por Sider-Perú en su planta de Chimbote y por Aceros Arequipa S.A. en su planta de Pisco. Uno de sus productos, la palanquilla, que se usa para el proceso de laminación de Ángulos y varillas lisas, es de material bastante parecido al del Acero ASTM A36. Sider-Perú fabrica, también, productos laminados planos, con la denominación ITINTEC P.341-083 y los suministra ya sea en forma de bobinas EG-24 o planchas PGE-24; su Punto de Fluencia es $F_y = 2400$ kg/cm²; su Esfuerzo de Fractura es $F_u = 4200$ kg/cm² y su ductilidad es 21% (en probetas de 200 mm); es similar al acero ASTM A36.

Con relación a los productos no planos, en Perú se laminan Ángulos hasta de 4 pulgadas, de lados iguales, canales pequeños y varillas lisas; se manufacturan tubos electro soldados hasta de 4 pulgadas y se ha comenzado la fabricación de Perfiles Estructurales Soldados de acuerdo a las normas ITINTEC 341-154. La tecnología del uso de estos últimos perfiles fue desarrollada en la UNI (3), (9).

2.2.6. Diseño económico en acero

Diseñar los elementos componentes de una estructura de acero implica no tan solamente el cálculo de las cargas actuantes en dicho sistema y la selección del perfil más ligero; sino que involucra otros aspectos que veremos a continuación:

- ✓ Uno de los primeros aspectos a tener en cuenta es el evitar tamaños de perfiles poco comunes, ya que una demanda de estos, generará costos de fabricación muy elevados.
- ✓ Otro detalle a tener en cuenta, se presenta cuando se seleccionan los perfiles más ligeros y no se toma en cuenta que cuando más cantidades de perfiles más detalladas se vuelven las conexiones. Todo esto implicaría un alto costo. Una buena propuesta es unificar el mayor número de perfiles posibles para evitar este tipo de costo.
- ✓ Los perfiles de acero en contacto con el concreto no deberían pintarse ni aquellos que tengan recubrimiento de material resistente al fuego.
- ✓ Al usar la misma sección el mayor número de veces posibles, ahorraríamos en costos de detallado, fabricación y montaje.
- ✓ Se deben escoger secciones fáciles de montar y mantener.

-
- ✓ La mayoría de edificios poseen en sus interiores ductos, tuberías que pueden adaptarse mejor si se selecciona un perfil adecuado.

2.3.- MÉTODOS DE DISEÑO

2.3.1.- ESPECIFICACIONES Y CÓDIGOS DE CONSTRUCCIÓN

Las normas y especificaciones han surgido porque delimitan los procedimientos y la toma de decisiones en el proceso de diseño de un determinado proyecto. Estas especificaciones son importantes porque derivan de la experiencia de edificaciones que han sufrido daños severos; y de procedimientos experimentales que han tenido un minucioso estudio en los laboratorios.

El uso de estas normas de construcción son de carácter general, que tienen ámbito de aplicación dentro de su jurisdicción correspondiente, ya sean regionales, locales, etc.

No rigen exclusivamente los proyectos, pero si contienen especificaciones de carácter propio (Especificaciones de acuerdo a la zona) que tienen que cumplirse obligadamente.

El proyectista debe tener el pleno conocimiento de estas especificaciones y actuar conforme a lo establecido por las normas.

2.3.2.-FILOSOFÍA DEL DISEÑO Y CONFIABILIDAD DE LAS ESPECIFICACIONES LRFD

Actualmente la norma peruana no restringe el uso de los métodos de diseño para estructuras basadas en acero. Tanto el método ASD (conocido por el método de esfuerzos permisibles, por sus siglas en inglés), como el método LRFD son permitidos para diseñar estos tipos de elementos.

Aunque se sabe bien, que el más antiguo método es el ASD (casi 100 años en uso) no se ha dejado de lado el método LRFD, aunque reciente (20 años aproximadamente), ya que da muestras de un mejor proceso racional de diseño que se fundamenta en los principios de la probabilidad.

El método del LRFD es el que acapara los intereses de los nuevos diseñadores debido a la reducción de los factores de costo como consecuencia de resultados en el dimensionamiento de los perfiles.

Por ser un reciente método, no ha sugerido mayor precaución en la aplicación de los procedimientos de diseño a los diferentes proyectos estructurales ya que ha surgido en base a minuciosos métodos probabilísticos de posibilidad de falla.

En este contexto se puede hablar del grado de confiabilidad del método LRFD refiriéndonos al porcentaje estimado de veces que la resistencia de una estructura será igual o excederá a la carga máxima aplicada a ella durante su vida estimada (50 años).

Se han desarrollado procedimientos para estimar la confiabilidad de los diseños y se ha llegado a establecer un criterio razonable en cuanto a porcentajes de confiabilidad para diferentes situaciones.

También se ha logrado determinar los factores Φ de resistencia, fundamentales para lograr el grado de confiabilidad antes mencionado.

Se debe tener en claro que cuando hablamos de 99.8% de confiabilidad, por ejemplo; no nos referimos a que de 1000 estructuras diseñadas al menos 2 van a desplomarse durante el periodo de vida útil; sino más bien a que 2 de esas estructuras diseñadas estarán en el rango plástico.

De ignorarse los principios estadísticos se incurriría en el error de aferrarse a un 100% de confiabilidad, lo que es incongruentemente ilógico.

A continuación se detalla un método abreviado probabilístico basado en la evaluación de la seguridad estructural, en donde se asume los efectos de las cargas Q y la resistencia R en sondeos variables.

La gráfica de distribución de frecuencias es la que se muestra a continuación.

FIGURA N° 2.11: Distribución de frecuencias Q y Resistencia R

Fuente: Tesis Carlos Nicolás Mendoza

La región sombreada vendría a ser lo que traduciríamos nosotros en un estado límite (falla estructural), donde la carga Q excedería a la resistencia R.

La distancia entre la línea de falla y la media de la función $[\ln(R/Q)]$ es definido como el múltiplo β de la desviación estándar de la función.

El múltiplo β es llamado el índice de confiabilidad; cuanto más grande el β más grande será el margen de seguridad.

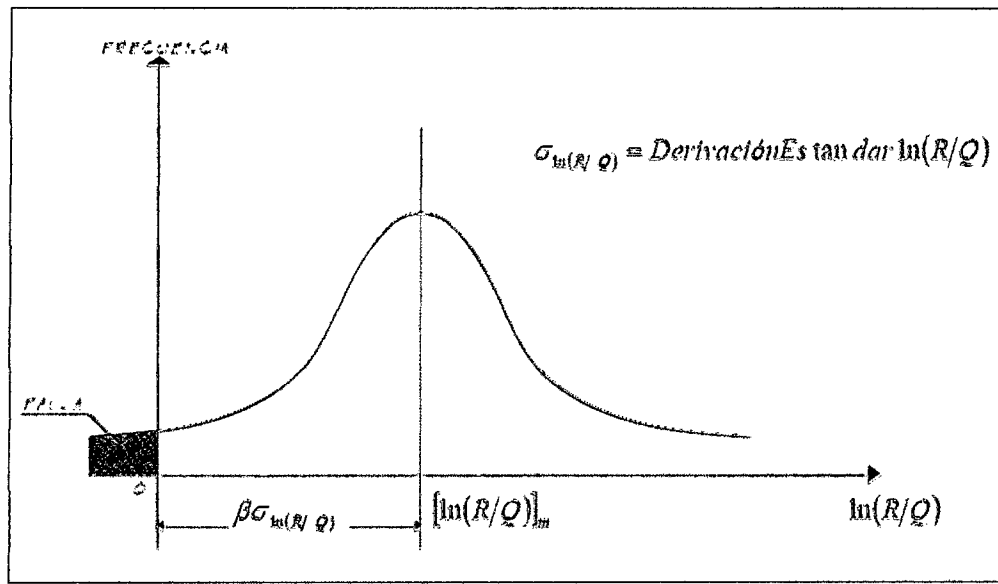

FIGURA N° 2.11: Índice de confiabilidad β

Fuente: Tesis Carlos Nicolás Mendoza

Se ha desarrollado una fórmula para calcular el β :

$$\beta = \frac{\ln(R_m / Q_m)}{\sqrt{V_R^2 + V_Q^2}}$$

Donde R_m y Q_m adoptan los valores medios de la resistencia y los efectos de las cargas respectivamente, en tanto que V_r y V_q son los coeficientes correspondientes de variación.

2.3.3 ESTADO LÍMITE

Existen dos tipos de estado límite: Los de resistencia y los de servicio.

Los primeros involucran todos los efectos que tienen que ver con la seguridad estructural y la capacidad de carga de la estructura

de las cuales podemos mencionar a las resistencias plásticas, de pandeo de fractura, de fatiga, de volteo, etc.

Los estados límites de servicio tienen que ver con aspectos asociados con el uso y la estética de la estructura, tales como deflexiones excesivas, deslizamientos, vibraciones y agrietamientos.

En el método LRFD las cargas de servicio se multiplican por factores de carga que son generalmente mayores a 1.0 y se obtienen las cargas factorizadas usadas para el diseño de la estructura. Las magnitudes de los factores de carga varían, dependiendo del tipo de combinación de cargas.

La estructura debe tener una resistencia última de diseño suficiente para resistir las cargas factorizadas. Esta resistencia resulta de multiplicar la resistencia nominal por un factor de resistencia que por lo general menor que 1.0.

Lo que se busca es disminuir la incertidumbre vinculada a las resistencias de los materiales, dimensiones y mano de obra.

2.3.4 FACTORES DE CARGA

Los factores de carga se han propuesto para alterar los valores nominales calculados con la finalidad de minimizar los riesgos que implican las incertidumbres de las cargas muertas y sobrecargas.

Como es más predecible calcular las cargas muertas que las cargas vivas; el valor del factor de carga aplicado para la carga viva es mayor que el aplicado para la carga muerta.

Las especificaciones LRFD presentan factores de carga y combinaciones de carga que fueron seleccionadas para usarse con las cargas mínimas recomendadas en el Estándar 7 – 93 de la American Society of Civil Engineers.

Las combinaciones usuales de carga consideradas en el LRFD están dadas en la especificación A.4.1 con las fórmulas A4 – 1 y A4 – 2.

En estas fórmulas se usan las abreviaturas D, para cargas muertas, L para cargas vivas. Lr para cargas vivas en techos, S para cargas de nieve y R para carga inicial de agua de lluvia o hielo. La letra U representa U representa la carga última.

En las especificaciones LRFD se da otra combinación de cargas para tomar en cuenta la posibilidad del levantamiento.

Esta condición se incluye para cubrir los casos donde se desarrollan fuerzas de tensión debidas a fuerzas de volteo; regirá sólo en edificios altos donde se presentan fuertes cargas laterales. En esta combinación las cargas muertas se reducen en un 10% para tomar en cuenta situaciones en las que se hayan sobreestimado.

2.3.5 FACTORES DE RESISTENCIA

Los factores de resistencia nos van a permitir estimar un valor de la resistencia que nos va a dar la seguridad de que el valor calculado es un resultado seguro y confiable para aplicarlo en nuestro diseño.

Con el factor de resistencia el proyectista reconoce implícitamente que la resistencia de un miembro no puede calcularse exactamente, debido a las imperfecciones en las teorías de análisis.

Para hacer la estimación se multiplica la resistencia nominal de cada elemento por un factor Φ de resistencia siempre menor que la unidad.

TABLA No 2.2.: Factores de resistencia

Factores de resistencia o ϕ	Situaciones
1.00	Aplastamiento en áreas proyectantes de pasadores, fluencia del alma bajo cargas concentradas, cortante en tornillos en juntas tipo fricción.
0.90	Vigas sometidas a flexión y corte, filetes de soldadura con esfuerzos paralelos al eje de la soldadura, soldaduras de ranura en metal base, fluencia de la sección total de miembros a tensión.
0.85	Columnas, aplastamiento del alma, distancias al borde y capacidad de aplastamiento en agujeros.
0.80	Cortante en el área efectiva de soldaduras de ranura con penetración completa, tensión normal al área efectiva de soldaduras de ranura con penetración parcial.
0.75	Tornillos a tensión, soldaduras de tapón o mescas, fractura en la sección neta de miembros a tensión.
0.65	Aplastamiento en tornillos (que no sean tipo A307)
T 0.60	Aplastamiento en cimentaciones de concreto.

Fuente: Tesis Carlos Nicolás Mendoza

Ventajas del LRFD

El buen criterio razonable de LRFD siempre ha sido atractivo y corresponde un permitido incentivo al mejor y más económico uso del material para algunas combinaciones de carga y una configuración estructural. El método puede también llevar probablemente a tener estructuras seguras en vista de la práctica arbitraria debajo del método de diseño por esfuerzos permisibles ASD de la combinación de las cargas muertas y las cargas vivas y tratándolas iguales.

El LRFD provee una variedad de opciones al diseñador.

CAPITULO III

ANÁLISIS Y PRESENTACIÓN DE

RESULTADOS

3. ANÁLISIS Y PRESENTACIÓN DE RESULTADOS

3.1. CONSIDERACIONES GENERALES

ANTECEDENTES

Para iniciar un proyecto hay que tomar en cuenta muchos aspectos relacionados con el terreno sobre el cual se ejecutará dicho proyecto, el uso que se le dará a la determinada edificación y muchos otros aspectos que son fundamentales y que conllevarán a tomar buenas decisiones ante posibles dificultades que se pudieran presentar.

3.1.1. CONSIDERACIONES PEDIALES

Es necesario tener el conocimiento de todos los detalles relacionados con la forma del edificio, la superficie del terreno sobre el cual se va a edificar, las redes de agua y alcantarillado, las redes eléctricas y teléfono. Se deben verificar las zonas y el estado en el que se encuentran estos tipos de servicio.

No debe dejarse la forma del terreno la pendiente que predomina en el sitio del proyecto, ni el ambiente que rodea el entorno, ya que de esto se puede determinar hasta cierto punto el grado de afectación relacionado con el clima.

Colindancias

Es de vital importancia conocer las características estructurales de las edificaciones vecinas, debido a que pueden

influir mucho en las presiones laterales sobre el terreno, y de donde se puede ver la capacidad del suelo ante determinados casos de presión.

Se puede deducir también de lo observado en las estructuras vecinas las posibles fallas en el terreno.

Topografía

El levantamiento topográfico va a ser de suma importancia porque suministra la información de la superficie del terreno. Al tener esta información podremos adaptar el proyecto a la forma y/o superficie del terreno para evitar la mayor cantidad de movimiento de tierras posible.

Proyecto Arquitectónico

Se recomienda que en el planeamiento arquitectónico el proyectista, de no ser un ingeniero estructural, se asesore de tal manera que el anteproyecto no se vea afectado por excesivas modificaciones y que satisfaga las necesidades para el cual se diseña.

Mecánica De Suelos

El estudio de mecánica de suelos es fundamental porque se pone en juego la edificación completa.

Este estudio proporciona las características físicas y mecánicas del suelo, la capacidad de resistencia y admisión de cargas al que puede sometersele.

3.1.2. CONSIDERACIONES DEL PROYECTO

3.1.2.1. LEVANTAMIENTO DEL TERRENO

DIRECCIÓN: Av. Pardo Cuadra 12 #1210;

Chimbote

Croquis de Ubicación del Proyecto

Fuente: Los tesisas

El terreno tiene una superficie de 600 m².

3.1.2.2. INFORME DE MECÁNICA DE SUELOS.

GEOLOGÍA Y SISMICIDAD

Geología

El examen de la zona en estudio permite inferir el subsuelo, el mismo que está constituido por depósitos heterogéneos y sedimentarios que están formados por suelo natural y arena limosa SP, muy compresibles que se presentan en espesores muy variables.

En cuanto a Geodinámica no se han presentado fenómenos que hayan afectado a la zona de trabajo ni se presentan formaciones que puedan afectarlo.

Sismicidad

El área del estudio ubicada en Av. Pardo Cdra. 12, #1210, distrito de Chimbote; provincia del Santa, departamento de Ancash, se encuentra en la Zona 3 de Sismicidad, de acuerdo al "Mapa de Zonificación Sísmica del Perú" de acuerdo a las Normas de Diseño Sismo-Resistente del Reglamento Nacional de Edificaciones.

Investigaciones de campo

El estudio consta de 11 calicatas.

Descripción de la conformación del subsuelo del área en estudio

C-1: De 0.00 - 0.05 se observa la presencia de una carpeta asfáltica, de 0.05 - 0.50 afirmado no compacto, de 0.50 - 1.80 se observa un estrato conformado por arena fina limosa, a partir de 1.80 de profundidad se encontró el nivel freático.

C-2: De 0.00 - 0.05 se observa la presencia de una carpeta asfáltica, de 0.05 - 0.50 afirmado no compacto, de 0.50 - 2.00 se observa un estrato conformado por suelo natural con arena fina limosa, a partir de 2.00 de profundidad se encontró el nivel freático.

C-3: De 0.00 - 0.05 se observa la presencia de una carpeta asfáltica, de 0.05 - 0.30 afirmado no compacto con presencia de plásticos y material de construcción, de 0.30 - 2.20 se observa un estrato conformado por suelo natural con arena fina limosa, a partir de 2.20 de profundidad se encontró el nivel freático.

C-4: De 0.00 - 0.05 se observa la presencia de una carpeta asfáltica, de 0.05 - 0.50 se observa una capa de afirmado de 0.50 - 2.00 se observa un estrato conformado por arena fina limosa, a partir de 2.00 de profundidad se encontró el nivel freático.

C-5: De 0.00 - 0.05 se observa la presencia de una carpeta asfáltica, de 0.05 - 0.40 se observa una capa de afirmado, de 0.40 - 2.10 se observa un estrato conformado por arena fina limosa, a partir de 2.10 de profundidad se encontró el nivel freático.

C-6: De 0.00 - 0.05 se observa la presencia de una carpeta asfáltica, de 0.05 - 0.40 capa de afirmado, de 0.40 - 2.10 se observa un estrato conformado por arena fina

limosa, a partir de 2.10 de profundidad se encontró el nivel freático.

C-7: De 0.00 - 0.05 se observa la presencia de una carpeta asfáltica, de 0.05 - 0.50 capa de afirmado, de 0.50 - 0.80 se observa un estrato conformado por suelo gravoso compacto de 0.80 - 2.30 observa un estrato conformado por arena fina limosa, a partir de 2.30 de profundidad se encontró el nivel freático.

C-8: De 0.00 - 0.05 se observa la presencia de una carpeta asfáltica, de 0.05 - 0.70 capa de afirmado no compacto, de 0.70 - 2.35 se observa un estrato conformado por arena fina limosa, a partir de 2.35 de profundidad se encontró el nivel freático.

C-9: De 0.00 - 0.05 se observa la presencia de una carpeta asfáltica, de 0.05 - 0.50 afirmado no compacto, de 0.50 - 2.10 se observa un estrato conformado por arena fina limosa, a partir de 2.10 de profundidad se encontró el nivel freático.

C-10: De 0.00 - 0.15 se observa terreno natural con presencia de pastos menores, raíces de grass y plantas secas, de 0.15 - 2.30 se observa un estrato conformado por arena fina limosa, a partir de 2.30 de profundidad se encontró el nivel freático.

C-11: De 0.00 - 1.00 se encuentra suelo natural con relleno de materiales de construcción 1.00 - 2.40 se

observa un estrato conformado por arena fina limosa, a partir de 2.40 de profundidad se encontró el nivel freático.

3.1.3. CONCLUSIONES Y RECOMENDACIONES DEL ESTUDIO DE SUELOS

Del análisis efectuado en el presente estudio, basándose en los trabajos de campo, ensayos de laboratorio, perfiles estratigráficos y cálculos realizados, se concluye:

Analizando los perfiles estratigráficos, los resultados de los ensayos de laboratorio y considerando las características estructurales del proyecto, las cimentaciones serán superficiales, se deberá tener en cuenta las vigas de cimentación, desplantados en suelo arena fina limosa color marrón claro de plasticidad negativa, húmeda, compacta, a una profundidad de 1.80m del terreno natural, le corresponden:

$$q_{ult} = 2.10 \text{ kg/cm}^2$$

$$\text{Factor de Seguridad} = 3$$

$$q_{ad} = q_{ult}/FS = 0.70 \text{ kg/cm}^2$$

a la profundidad de 1.80 m. desde la superficie.

De los resultados obtenidos del ensayo de Análisis Químico de Sales Agresivas al Concreto, realizado en una muestra de la calicata C-S de 1.10 a 2.00 m. de profundidad, se tiene:

Cloruros como ión Cl^- (ppm) = 1,823.30

Sulfatos con ión SO_4 (ppm) = 1,650.00

Estos valores determinan que habrá agresividad al concreto debiéndose utilizar Cemento Pórtland Tipo V, en los elementos en contacto con el terreno.

Las conclusiones y recomendaciones del presente estudio constituyen una opinión técnica salvo mejor parecer.

Las conclusiones y recomendaciones del presente son sólo aplicables al área estudiada.

3.2. ESTRUCTURACIÓN:

El edificio tiene una planta de 25.50 m X 14.00 m con paños de 8.5 m en la dirección principal y 4.67 m en la otra dirección.

La altura entre ejes de vigas para la modelación de los pórticos se establece:

Altura de piso a cielorraso:	2.70
Altura de entrepiso:	0.20
Espacio para Instalaciones:	<u>0.25</u>
Altura total:	3.15

3.2.1. CARGAS DE DISEÑO: (RNE)

Cargas muertas que actúan sobre los pisos:

Peso losa compuesta, $t = 0.1\text{m}$: 37.28 psf (lbs/pie²)182
Kg/m²

Piso terminado:	20.00 psf	100 Kg/m ²
Cables y ductos colgados:	10.00 psf	50 Kg/m ²
Cielorraso:	6.00 psf	30 Kg/m ²
Tabiquería móvil:	<u>20.00 psf</u>	<u>100 Kg/m²</u>
Total Carga Muerta:	93.28 psf	462 Kg/m²

Para este caso se considerará la misma carga muerta en el techo tercer piso.

Adicionalmente se toma una carga correspondiente a fachada la cual estará sujeta a la estructura de acuerdo con la recomendación del fabricante.

Se asumirá que las cargas de la fachada se aplican a los pórticos en las intersecciones de los elementos principales.

Consideramos un peso de 75 Kg/m² de fachada.

$$P = 75A = \frac{75[3.15(8.5)]}{1000} = 2 \text{ Tn}$$

Estas cargas actúan hacia abajo como cargas de gravedad.

Carga viva:

El edificio será de oficinas considerandose una carga viva de 250 kg/m² según la norma NTE 020.

3.2.1.1.- ESTRUCTURACIÓN DE ENTREPISOS:

Estructuración – Planta

Elevación - Pórtico 1

3.2.1.2. DISEÑO DE VIGAS DE PISO

$d=L/24=16x12/24=8''$, por lo tanto se considera un perfil

W8.

Carga última:

$$W_D = 1.42 \times 462 = 656.04 \text{ Kg/m}$$

$$W_L = 1.42 \times 250 = 355.00 \text{ Kg/m}$$

$$W_u = 1.2(656.04) + 1.6(355.00) = 1355.28 \text{ Kg/m} = 1.36$$

Tn/m

$$M_u = (1/8)w_u L^2 = (1/8) (1.36) (4.67)^2 = 3.7 \text{ Tn-m (26.76 Kip-ft)}$$

Longitud entre soporte lateral: $L_b = 1.5' = 0.46 \text{ m} = 18''$ (para evitar el pandeo lateral).

Seleccionamos el perfil W8x10, que tiene un $\phi_b M_p =$
33 Kip – pie para acero A-572 grado 50 (Proveedor:
SIDERPERÚ – GERDAU).

Sobre estos elementos se asentara una losa
compuesta: ACERO DECK + Concreto $f'_c=210$ kg/cm² que
pesa por m² según catálogo 182.3 kg/m² / $4.89 = 37.28$
lbs/pie².

3.2.1.3. SELECCIÓN PRELIMINAR DE VIGAS:

Con un momento de $-1/11w_uL^2$, estimamos el
momento negativo en las vigas principales:

$$L=8.5 \text{ m (28')}$$

$$w_u=1.2 (462) + 1.6 (250) = 954.4 \text{ kg/m}^2$$

$$w_u=0.954 \times 4.67 = 4.46 \text{ Tn/m}$$

$$M_u = (1/11)(4.46)(8.5)^2 = 40.28 \text{ Tn-m (291.35 Kip-ft)}$$

$$d = L/20 = 28 \times 12 / 20 = 17''$$

Seleccionamos un perfil: W18, en las tablas de
diseño tenemos el W18X40

Con un $M_u=294$ Klbs-pie.

Para las vigas transversales, consideraremos tentativamente, $d=16 \times 12 / 20 = 10'$, escogemos un perfil W10x30 $M_u= 137$ Klbs-pie. (25% mas liviano que las vigas principales).

3.2.1.4. SELECCIÓN PRELIMINAR DE COLUMNAS:

$$\text{Área tributaria} = 4.67 \times 8.5 = 40 \text{ m}^2$$

$P_u = 5 \times 0.95 \times 40 = 190 \text{ Tn}$ (Columna interior más crítica).

Considero un perfil W14 al 60% en compresión axial, entonces busco un perfil W14 que soporte $190 / 0.60$

= 317 Tn (700 Klbs) con una longitud efectiva $KL = 1.0L = 3.15 \text{ m. (10.33')}$.

Fuente: Manual AISC - LRFD

Seleccionamos tentativamente un perfil W14x74.

CAPITULO IV

CONCLUSIONES Y RECOMENDACIONES

4.1 CONCLUSIONES

Se realizó el análisis de un edificio de acero por el método de los estados límites, determinando las cargas actuantes en los diferentes elementos del sistema estructural (vigas, columnas, etc.) recurriendo a las Especificaciones AISC donde se seleccionó el perfil adecuado según la capacidad admitida por cada perfil y realizar el diseño preliminar de todo el sistema verificando los valores obtenidos hasta obtener el resultado adecuado.

Se calcularon los esfuerzos en todos los elementos del sistema y se verificaron las deformaciones en cada nivel de la estructura.

Se realizó el diseño final del sistema estructural, empleando las combinaciones de carga recomendadas por el manual LRFD.

Se detallaron y especificaron los resultados del diseño en planos.

Los desplazamientos máximos de los centros de las losas son: 0.169m, 0.143m, 0.117m, 0.084m, 0.047m. Del 5to, 4to, 3er, 2do y 1er piso respectivamente.

El valor del desplazamiento relativo de entrepiso en el último nivel es de 0.009839 en la dirección "X" y 0.003345 en la dirección "Y", el cual está bajo el límite del valor permitido por la norma, que es de 0.010.

El valor máximo de la reacción en el apoyo más crítico es de 302.85 Ton, ubicado en los apoyos 2 y 15.

Los valores máximos en las reacciones y desplazamientos se obtienen con la combinación $1.2D \pm 1.0E \pm 0.5L$, en donde intervienen las cargas sísmicas, muertas y vivas respectivamente.

El valor más alto del momento en columnas es de 307.65 Ton, en las columnas C5, C8, C9, C12.

4.2 RECOMENDACIONES

El método de los estados límites es el método que debe ser usado en comparación con el método ASD, ya que emplea procedimientos de análisis mucho más racionales y que por consiguiente generan resultados más aproximados a la realidad.

Para desarrollar un proyecto estructural de una sistema en acero hay que tener en cuenta muchos factores para luego no sobrevalorar el presupuesto de dicho proyecto. Se deben tener en cuenta los factores tales como, la homogeneidad de los elementos estructurales (En cuanto a las dimensiones), el transporte de los materiales, el valor de los materiales a usar, el costo de la mano de obra, el detallado de las conexiones o el tipo de conexión a usar, etc. Haciendo un balance general de todos estos factores se pueden aminorar costos que están vinculados al costo del proyecto en general.

Se recomienda verificar el límite del desplazamiento relativo de entrepiso calculado y verificarlo con el especificado por la norma (Tabla 8, Art. 15), el cual no debe exceder la fracción de altura de entrepiso indicada.

Se recomienda identificar el mayor valor de la reacción en la base y seleccionar ese valor para que sirva como parámetro de referencia al diseñar la cimentación.

Se recomienda uniformizar los perfiles usados como viguetas en la losa colaborante.

Se recomienda usar los perfiles adecuados que resistan los momentos máximos calculados en el análisis.

DATOS PARA EL ESPECTRO SÍSMICO

Parámetros sísmicos		
Factor de zona, Z	0.4	Zona 3, Chimbote
Factor de uso, U	1.0	Edificaciones comunes
Parámetro de suelo, S	1.0	S1, suelo muy rígido ($T_p = 0.4$)
Factor de amplificación dinámica, C	2.5	$C = 2.5 \left(\frac{T_p}{T} \right) \leq 2.5, T = \frac{h_n}{C_T}, C_T = 35$
Coefficiente de reducción, R	6.0	

Período fundamental de la estructura: $T = h_n / C_T = 0.34$; ($C_T = 35$ y $h_n = 11.89\text{m}$).

Factor de amplificación sísmica: $C = 2.5$ ($C = 2.94 > 2.5$, considero $C = 2.5$).

Para estimar la respuesta estructural máxima esperada "r" se utiliza la combinación

$$r = 0.25 \sum_{i=1}^m |r_i| + 0.75 \sqrt{\sum_{i=1}^m r_i^2}$$

Donde:

- $\sum_{i=1}^m |r_i|$ = Suma de los valores absolutos de las respuestas elásticas correspondientes al modo "i" (ABS).
- $\sqrt{\sum_{i=1}^m r_i^2}$ = Raíz cuadrada de la suma de los cuadrados de las respuestas elásticas correspondientes al modo "i" (RCSC).

Damping: 0.05

Excentricidad: 5%

Las combinaciones y factores de carga consideradas son:

- Combinación 1: 1.2D±1.6L
- Combinación 2: 1.2D±1.0E±0.5L
- Combinación 3: 0.9D±1.0E

Donde:

D=Carga muerta (Dead load)

L=Carga viva (Live load)

E=Carga sísmica (Earthquake load)

REGISTRO DE TRABAJO DE INVESTIGACIÓN

I. DATOS GENERALES:

UNIVERSIDAD: UNIVERSIDAD NACIONAL DEL SANTA

ESCUELA O CARRERA PROFESIONAL: INGENIERÍA CIVIL

TÍTULO DEL TRABAJO:“ANÁLISIS Y DISEÑO DE UN EDIFICIO DE
ACERO POR EL MÉTODO DE LOS
ESTADOS LÍMITES EN LA CIUDAD DE
CHIMBOTE”

ÁREA DE INVESTIGACIÓN: ESTRUCTURAS

AUTOR(ES):

- DNI: 45238355 BOLAÑOS RUIZ MARVIN ROY
- DNI: 44805844 CUZMA GONZALES JUAN CARLOS

TÍTULO PROFESIONAL A QUE CONDUCE:TÍTULO PROFESIONAL
DE INGENIERO CIVIL

AÑO DE APROBACIÓN DE LA SUSTENTACIÓN: 2014

II. CONTENIDO DEL RESUMEN

- **PLANTEAMIENTO DEL PROBLEMA:**

Existe una nula atención que se le brindan a los proyectos estructurales de acero en nuestro entorno debido a varios factores, como son falta de conocimientos en los procedimientos de diseño, la idea de que toda estructura basada en sistemas de acero en gran medida es costosa; el temor de que dichas construcciones sean inestables.

¿Qué se logrará con el análisis y diseño de un edificio de acero por el método de los estados límites en la ciudad de Chimbote?

- **OBJETIVOS**

OBJETIVO GENERAL:

- Realizar el análisis y diseño de un edificio de acero por el método de los estados límites.

OBJETIVOS ESPECÍFICOS:

- Calcular los esfuerzos y deformaciones de un sistema estructural de acero.
- Diseñar los elementos estructurales por el método de los estados límites.
- Detallar en planos CAD los resultados del diseño.

- **HIPÓTESIS:**

Si se aplican los procedimientos adecuados que involucra el método de los estados límites en el análisis y cálculo de los elementos componentes de un edificio metálico; entonces se tendrá como resultado, un diseño final óptimamente estructurado que servirá como guía y ejemplo para futuros proyectos basados en sistemas de acero.

- **MARCO TEORICO:**

El método del LRFD es el que acapara los intereses de los nuevos diseñadores debido a la reducción de los factores de costo como consecuencia de resultados en el dimensionamiento de los perfiles.

Por ser un reciente método, no ha sugerido mayor precaución en la aplicación de los procedimientos de diseño a los diferentes proyectos estructurales ya que ha surgido en base a minuciosos métodos probabilísticos de posibilidad de falla.

En este contexto se puede hablar del grado de confiabilidad del método LRFD refiriéndonos al porcentaje estimado de veces que la resistencia de una estructura será igual o excederá a la carga máxima aplicada a ella durante su vida estimada (50 años). Se han desarrollado procedimientos para estimar la confiabilidad de los diseños y se ha llegado a establecer un criterio razonable en cuanto a porcentajes de confiabilidad para diferentes situaciones.

También se ha logrado determinar los factores Φ de resistencia, fundamentales para lograr el grado de confiabilidad antes mencionado.

- **CONCLUSIONES Y/O RECOMENDACIONES:**

CONCLUSIONES

Se realizó el análisis de un edificio de acero por el método de los estados límites, determinando las cargas actuantes en los diferentes elementos del sistema estructural (vigas, columnas, etc.) recurriendo a las Especificaciones AISC donde se seleccionó el perfil adecuado según la capacidad admitida por cada perfil y realizar el diseño preliminar de todo el sistema verificando los valores obtenidos hasta obtener el resultado adecuado.

Se calcularon los esfuerzos en todos los elementos del sistema y se verificaron las deformaciones en cada nivel de la estructura.

Se realizó el diseño final del sistema estructural, empleando las combinaciones de carga recomendadas por el manual LRFD.

Se detallaron y especificaron los resultados del diseño en planos.

Los desplazamientos máximos de los centros de las losas son: 0.169m, 0.143m, 0.117m, 0.084m, 0.047m. Del 5to, 4to, 3er, 2do y 1er piso respectivamente.

El valor del desplazamiento relativo de entrepiso en el último nivel es de 0.009839 en la dirección "X" y 0.003345 en la dirección "Y", el cual está bajo el límite del valor permitido por la norma, que es de 0.010.

El valor máximo de la reacción en el apoyo más crítico es de 302.85 Ton, ubicado en los apoyos 2 y 15.

Los valores máximos en las reacciones y desplazamientos se obtienen con la combinación $1.2D \pm 1.0E \pm 0.5L$, en donde intervienen las cargas sísmicas, muertas y vivas respectivamente.

El valor más alto del momento en columnas es de 307.65 Ton, en las columnas C5, C8, C9, C12.

RECOMENDACIONES

El método de los estados límites es el método que debe ser usado en comparación con el método ASD, ya que emplea procedimientos de análisis mucho más racionales y que por consiguiente generan resultados más aproximados a la realidad.

Para desarrollar un proyecto estructural de una sistema en acero hay que tener en cuenta muchos factores para luego no sobrevalorar el presupuesto de dicho proyecto. Se deben tener en cuenta los factores tales como, la homogeneidad de los elementos estructurales (En cuanto a las dimensiones), el transporte de los materiales, el valor de los materiales a usar, el costo de la mano de obra, el detallado de las conexiones o el tipo de conexión a usar, etc. Haciendo un balance general de todos estos factores se pueden aminorar costos que están vinculados al costo del proyecto en general.

Se recomienda verificar el límite del desplazamiento relativo de entrepiso calculado y verificarlo con el especificado por la norma (Tabla 8, Art. 15), el cual no debe exceder la fracción de altura de entrepiso indicada.

Se recomienda identificar el mayor valor de la reacción en la base y seleccionar ese valor para que sirva como parámetro de referencia al diseñar la cimentación.

Se recomienda uniformizar los perfiles usados como viguetas en la losa colaborante.

Se recomienda usar los perfiles adecuados que resistan los momentos máximos calculados en el análisis.
